Growth and Decay Point Clouds

This point cloud drawing is a type of discrete render of the model, instead of a stable object. This technique animates the surface through densities and layers rather than lines. Where the points gather, the form thickens into something solid and legible, whereas, where they are thin and opaque the surface dissolves into atmosphere, blending the figure into the background. I selected this drawing because it most directly shows the dual processes driving the project. Growth is represented the accumulation and hierarchy of points, while decay is found as a soft, scattered silhouette, where the structure sheds particles back into the surrounding void and vanishes bits by bits.

I chose for Project 1 this drawing because its layered plan and section reveal the underlying geometric logic of nested circles that generates the entire form. For project 2 I am displaying this drawing because its exploded axonometric breaks the model into its individual components, exposing how the form accumulates through repetition. Lastly for Project 3 I chose this drawing because its unrolled surface translates the three-dimensional form into a flat, striped field, animating the surface as a continuous skin marked by the rhythm of its construction.
